

# Estimating causal effects of policy interventions Workshop ODISSEI / SICSS

Erik-Jan van Kesteren (& Oisín Ryan)

## Today we use R. You like python better? There's a book for that:

Causal Inference for The Brave and True

## https://is.gd/sicsscausal

#### **About me**

#### **Erik-Jan van Kesteren**

- Team lead ODISSEI SoDa team
- Background in statistics / social science
- Assistant professor @ Methods & Statistics UU

#### Some stuff I work on:

Latent variables, high-dimensional data, optimization, regularization, visualisation, Bayesian statistics, multilevel models, spatial data, generalized linear models, privacy, synthetic data, high-performance computing, software development, open science & reproducibility

#### Today's Goal

A brief practical introduction on evaluating the causal effects of policy interventions

### The plan

- Part 1 Policy interventions, causal inference, and basic methods
- Part 2 Interrupted time series and regression discontinuity
- Lunch
- Part 3 The synthetic control method
- Conclusion/discussion

## **Policy Evaluations**

**Evaluating** what the **effect** of implementing a particular **policy** or **intervention** was on some outcome of interest

#### **Examples:**

- What was the effect of raising the maximum speed limit on road deaths?
- What effect did introducing student loans have on post-graduation debt levels?
- Did introducing an after-school programme in disadvantaged neighbourhoods lead to improved educational outcomes in children from that neighbourhood?

## **Policy evaluations**

Register data is great for this purpose!

- Historical data availability
- Wide range of variables to create outcome of interest
- Many options to create, inspect, and match potential control units (e.g., other schools, neighbourhoods)

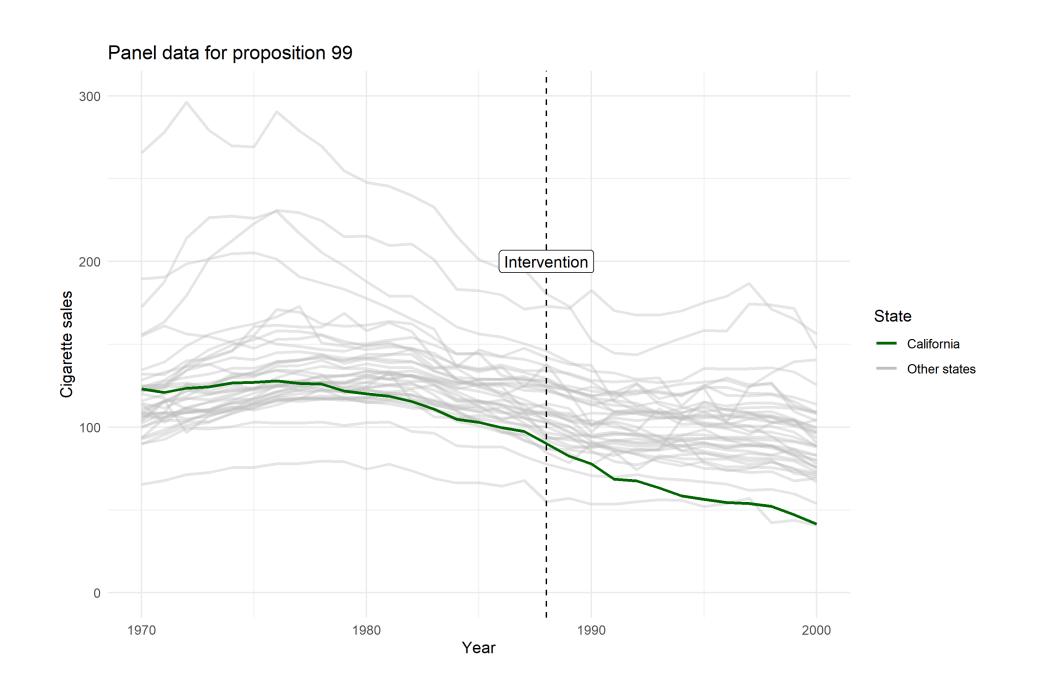

## Running Example: Proposition 99

## **Proposition 99**

• A famous example in causal inference literature

Abadie, A., Diamond, A., & Hainmueller, J. (2010). Synthetic control methods for comparative case studies: **Estimating the effect of California's tobacco control program**. Journal of the American statistical Association, 105(490), 493-505.

- In 1988, the state of California imposed a 25% tax on tobacco cigarettes
- Total savings in personal health care expenditure until 2004 is \$86 billion (Lightwood et al., 2008)

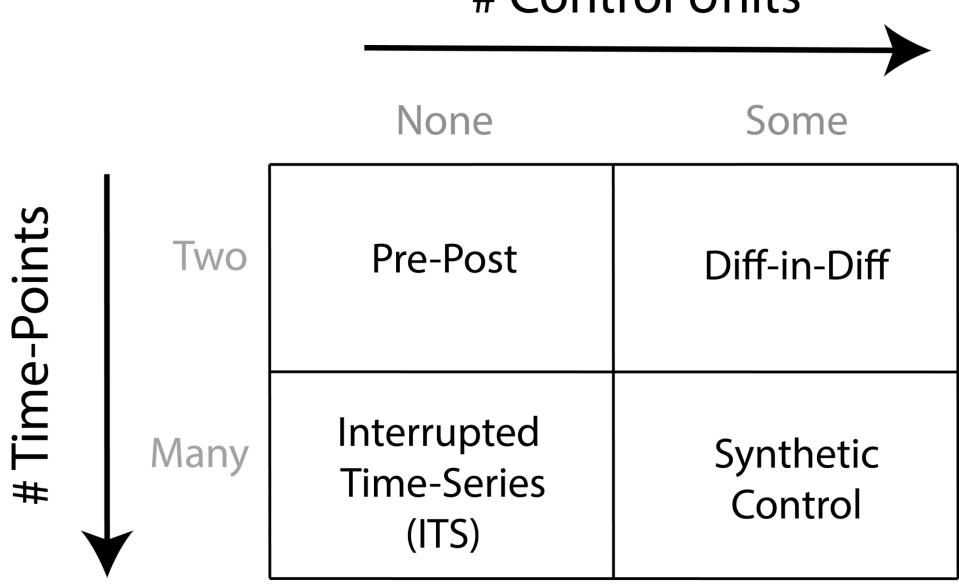

#### Methods for Policy Evaluation

Many different methods have been developed to answer these types of research questions

#### Differing in:

- The amount and type of information they use
  - Number of time-points and potential "control" units
- The specific statistical approach they take
- The types of assumptions they make

#### # Control Units

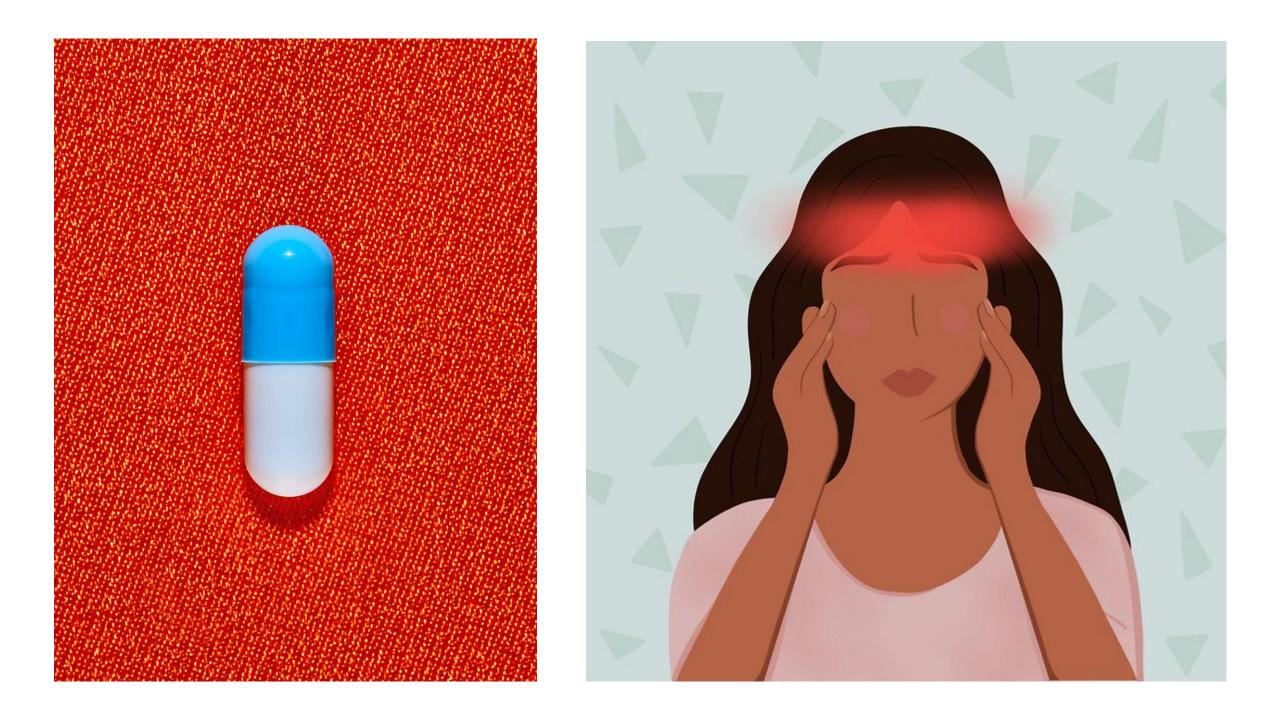

## Causal Inference: A primer

#### **Potential Outcomes**

**Causal inference** is (broadly) concerned with using **data** to estimate what the effect is of **intervening or changing** the value of one or more **variables**.

Using the **potential outcomes** framework, we can define causal inference as a *missing data problem* 

#### **Potential Outcomes: notation**

- Let  $Y_i$  represent your headache level (high is bad)
- Let  $A_i$  be whether you take aspirin or not ( $A_i = 1$  you take it,  $A_i = 0$  you don't)

There are two possible versions of the outcome variable

- $Y_i^1$  your headache level **if you would take aspirin**
- $Y_i^0$  your headache level **if you would not take aspirin**

#### **Causal Effects**

We can define the **causal effect** of taking aspirin on your headache levels as the difference in potential outcomes

$$CE_i = Y_i^1 - Y_i^0$$

The fundamental problem of causal inference: You only ever observe one of the potential outcomes!

#### **Data and Potential Outcomes**

ID	Y	A
1	7	0
2	9	0
3	6	0
4	5	0
5	6	0
6	2	1
7	3	1
8	1	1
	•••	
I	2	1

#### **Data and Potential Outcomes**

ID	Y	A	$Y^0$	$Y^1$
1	7	0	7	NA
2	9	0	9	NA
3	6	0	6	NA
4	5	0	5	NA
5	6	0	6	NA
6	2	1	NA	2
7	3	1	NA	3
8	1	1	NA	1
I	2	1	NA	2

#### **Data and Potential Outcomes**

ID	Y	A	<i>Y</i> <sup>0</sup>	<i>Y</i> <sup>1</sup>
1	7	0	7	NA
2	9	0	9	NA
3	6	0	6	NA
4	5	0	5	NA
5	6	0	6	NA
6	2	1	NA	2
7	3	1	NA	3
8	1	1	NA	1
I	2	1	NA	2

In cross-sectional settings, we typically aim to make inferences about the **average causal effect.** This is known as a **causal estimand:** 

$$ACE = E[Y^1] - E[Y^0]$$

In a **Randomized Controlled Trial,** we often use the difference in treated and untreated groups as an **estimator** of this causal effect:

$$\widehat{ACE} = E[Y | A = 1] - E[Y | A = 0]$$

ID	Y	A	$Y^0$	$Y^1$
1	7	0	7	NA
2	9	0	9	NA
3	6	0	6	NA
4	5	0	5	NA
5	6	0	6	NA
6	2	1	NA	2
7	3	1	NA	3
8	1	1	NA	1
I	2	1	NA	2

In cross-sectional settings, we typically aim to make inferences about the **average causal effect.** This is known as a **causal estimand**:

$$ACE = E[Y^1] - E[Y^0]$$

In a **Randomized Controlled Trial**, we often use the (sample) difference in treated and untreated groups as an **estimator** of this causal effect:

$$\widehat{ACE} = E[Y | A = 1] - E[Y | A = 0]$$

ID	Y	A	$Y^0$	$Y^1$
1	7	0	7	NA
2	9	0	9	NA
3	6	0	6	NA
4	5	0	5	NA
5	6	0	6	NA
6	2	1	NA	2
7	3	1	NA	3
8	1	1	NA	1
I	2	1	NA	2

### Causal Inference Assumptions

This type of **inference** about causal effects from **observed data** is only possible under certain **conditions** or **assumptions** 

#### **Exchangeability**

- If we were to reverse treatment assignment we would observe the same group differences. Information is exchangeable between groups
- Basically: absence of **confounder variables** 
  - E.g., People who have bad headaches choose to take the aspirin
- **RCTs** are powerful because **randomization** ensures exchangeability. But in principle this kind of inference is possible from non-RCT designs
- In practice we need conditional exchangeability; to control for confounders!

### Causal Inference Assumptions

This type of **inference** about causal effects from **observed data** is only possible under certain **conditions** or **assumptions** 

#### Stable Unit Treatment Value (also known as SUTVA)

- No Interference: The potential outcomes of one unit does not depend on the treatment assigned to another unit.
  - No "spillover": My taking an aspirin does not influence your headache levels
- Consistency: Only one version of treatment, treatment is unambiguous
- I can directly observe one of the potential outcomes. If you receive treatment, then for you I observe  $Y_i = Y_i^1$

### Causal Inference Assumptions

- These two often appear in causal inference
- Need to deal with confounders and no interference

#### NB:

- Other assumptions or conditions may also be needed
- Depends on design and analytic approach you take

### Causal inference for policies

**Policy evaluation** is a special case of causal inference:

- Usually: one unit observed repeatedly over time
- At some point in time  $(T_0)$  an **intervention** takes place

**Pre-intervention** we observe  $Y_t^0$  and **post-intervention**  $Y_t^1$ 

Time	$Y_t$	$A_t$
1	7	0
2	9	0
3	6	0
4	5	0
5	6	0
6	2	1
7	3	1
8	1	1
$\overline{T}$	2	1

Time	$Y_t$	$A_t$	$Y_t^0$	$Y_t^1$
1	7	0	7	NA
2	9	0	9	NA
3	6	0	6	NA
4	5	0	5	NA
5	6	0	6	NA
6	2	1	NA	2
7	3	1	NA	3
8	1	1	NA	1
T	2	1	NA	2

#### **Causal Effects of Policies**

Estimate the **causal effect of the policy intervention** as difference between:

- (a) the **observed outcome** <u>after</u> the policy was introduced
- (b) What the outcome would have been without the intervention

$$CE_t = Y_t^1 - Y_t^0$$

where  $t > T_0$  (i.e., the post-intervention time period)

Time	$Y_t$	$A_t$	$Y_t^0$	$Y_t^1$
1	7	0	7	NA
2	9	0	9	NA
3	6	0	6	NA
4	5	0	5	NA
5	6	0	6	NA
6	2	1	NA	2
7	3	1	NA	3
8	1	1	NA	1
T	2	1	NA	2

Time	$Y_t$	$A_t$	$Y_t^0$	$Y_t^1$
1	7	0	7	NA
2	9	0	9	NA
3	6	0	6	NA
4	5	0	5	NA
5	6	0	6	NA
6	2	1	NA	2
7	3	1	NA	3
8	1	1	NA	1
T	2	1	NA	2

## The problem of estimating the effect of a policy intervention is equivalent to the problem of estimating $Y_t^0$

Abadie, A. (2021). Using synthetic controls: Feasibility, data requirements, and methodological aspects. Journal of Economic Literature, 59(2), 391-425.

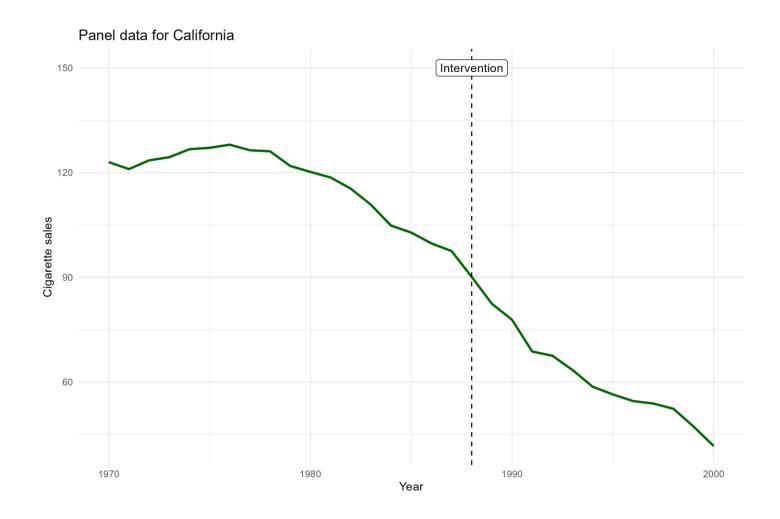

# Estimating the causal effect Basic methods

#### # Control Units

Some None # Time-Points Two Pre-Post Diff-in-Diff Interrupted Many Synthetic Time-Series Control (ITS)

## Pre-Post Estimator

We use only the cigarette sales time series for California

• We want to estimate the following quantity:

$$\overline{CE}_{post} = \overline{Y}_{post}^{1} - \overline{Y}_{post}^{0}$$

- But we cannot observe  $\bar{Y}^0_{post}$ !
- Solution: replace  $\bar{Y}^0_{post}$  by  $\bar{Y}^0_{pre}$ , which is observable

$$\overline{CE}_{post} = \overline{Y}_{post}^{1} - \overline{Y}_{pre}^{0}$$

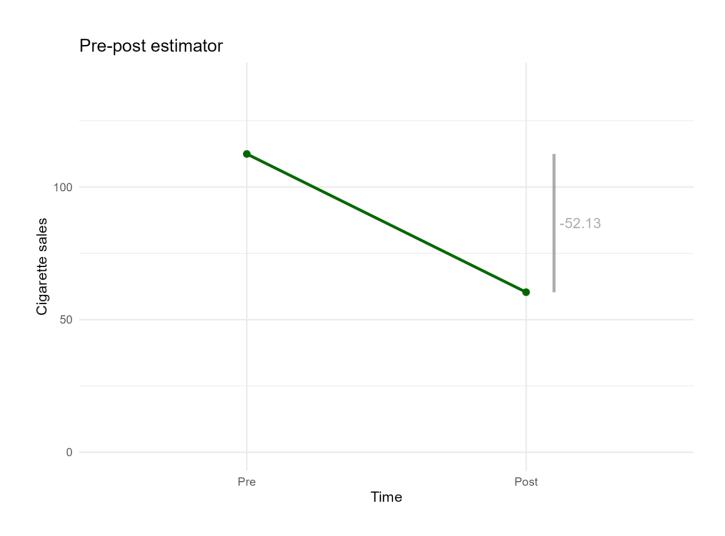

## Pre – Post analysis

Time	$Y_t$	$A_t$	$Y_t^0$	$Y_t^1$	
1	7	0	7	NA	
2	9	0	9	NA	
3	6	0	6	NI A	$\overline{Y}_{pre}^{0}$
4	5	0	5	NA	pre
5	6	0	6	NA	
6	2	1	NA	2	
7	3	1	NA	3	
8	1	1	NA	1	$\overline{Y}_{post}^1$
					post
$\overline{T}$	2	1	NA	2	

## Pre – Post analysis

Time	$Y_t$	$A_t$	$Y_t^0$	$Y_t^1$	
1	7	0	7	NA	
2	9	0	9	NA	
3	6	0	6	NI A	$\bar{Y}_{nre}^0 \sim$
4	5	0	5	NA	$\overline{Y}_{pre}^{0}$ $A_{sum_{equal_{ro}}}$
5	6	0	6	NA	Cqu <sub>s</sub>
6	2	1	NA	2	6
7	3	1	NA	3	`
8	1	1	NA	1	$\bar{Y}_{post}^1 - \bar{Y}_{post}^0$
					post
T	2	1	NA	2	<b>↑</b>
	•	•			

$$\overline{CE}_{post} = \overline{Y}_{post}^{1} - \overline{Y}_{post}^{0}$$

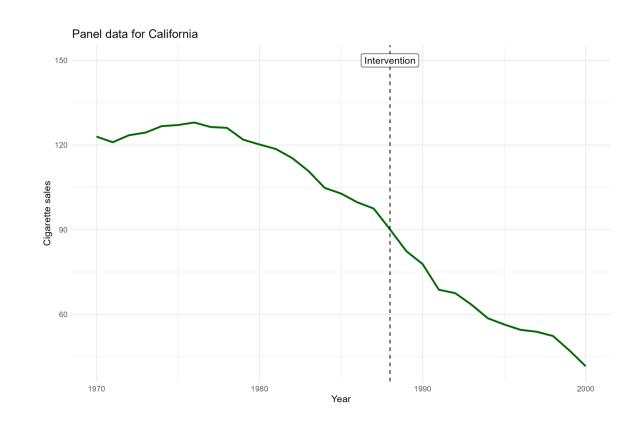

Most important / strict assumption:

#### No trend in time

- Remember: we assumed  $\bar{Y}^0_{post} = \bar{Y}^0_{pre}$
- We assume the pre-post difference is caused by intervention only
- If trend exists, then the effect of trend and of intervention cannot be distinguished

- Is there a trend in time, independent of the intervention?
- How much of prepost difference is caused by intervention?

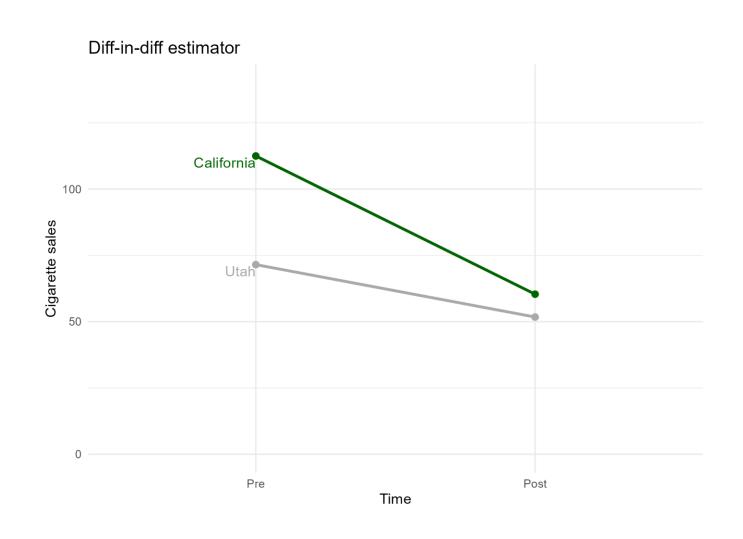

"transparent and often at least superficially plausible"

Angrist, J. D. and Krueger, A. B. (1999). Empirical strategies in labor economics. In Handbook of labor economics, volume 3, pages 1277–1366. Elsevier.

- Used a lot in economics
- There is a lot of discussion around this topic
- We will explain the basic method here
- There are a lot of possible extensions!

Time	$Y_t$	$A_t$	$Y_t^0$	$Y_t^1$	$C_{1t}$
1	7	0	7	NA	2
2	9	0	9	NA	6
3	6	0	6	NA	4
4	5	0	5	NA	2
5	6	0	6	NA	1
6	2	1	NA	2	3
7	3	1	NA	3	2
8	1	1	NA	1	4
T	2	1	NA	2	3

• Like before, we estimate the following quantity:

$$\overline{CE}_{post} = \overline{Y}_{post}^{1} - \overline{Y}_{post}^{0}$$

- Now, we assume there is an effect of time:  $\beta \cdot Time$
- We can represent unobservable  $ar{Y}_{post}^0$  as

$$\bar{Y}_{post}^0 = \bar{Y}_{pre}^0 + \beta \cdot Time$$

- But the trend  $\beta \cdot Time$  is also unobservable!
- Solution: assume equal trends for Utah and California

$$\beta \cdot Time = (\bar{C}_{post}^0 - \bar{C}_{pre}^0)$$

• Thus, our model for the counterfactual is:

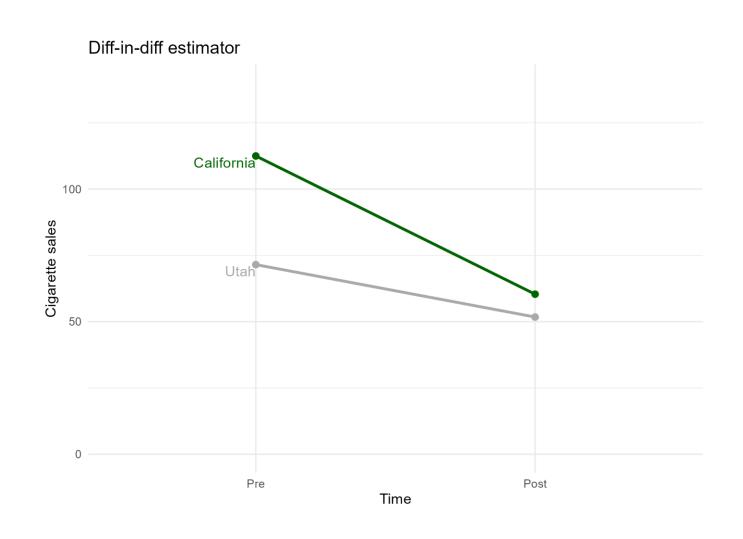

$$\bar{Y}_{post}^0 = \bar{Y}_{pre}^0 + (\bar{C}_{post}^0 - \bar{C}_{pre}^0)$$

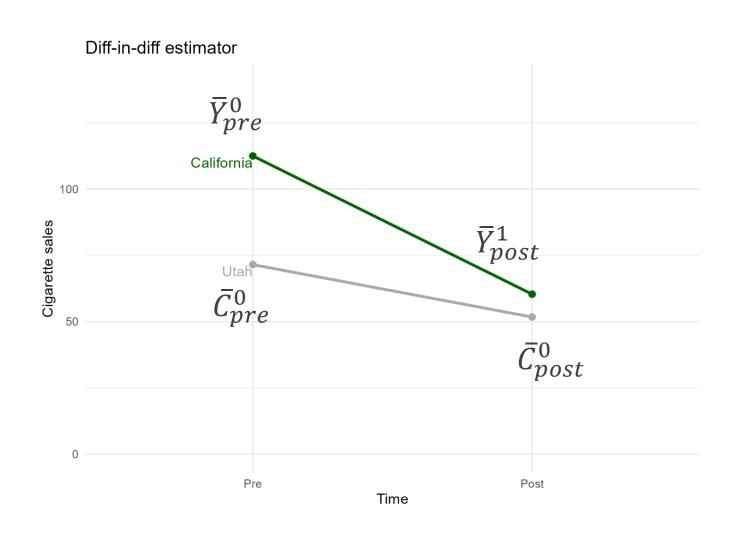

• Plugging this into the causal effect equation:

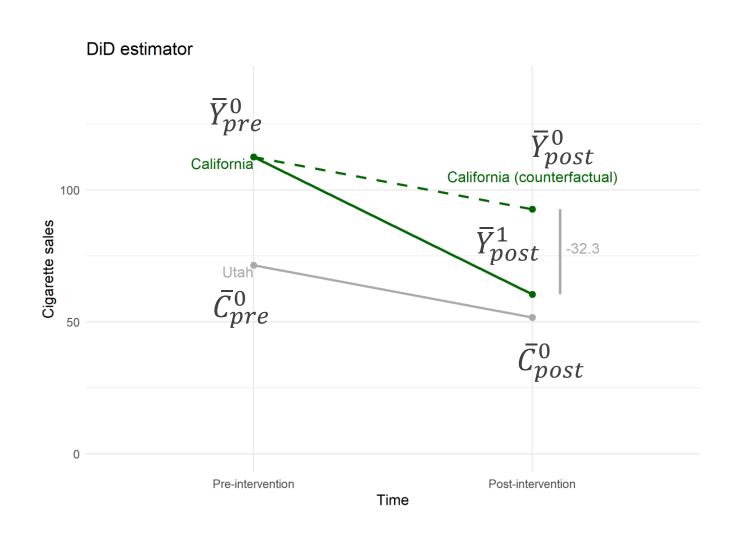

$$\overline{CE}_{post} = (\overline{Y}_{post}^{1} - \overline{Y}_{pre}^{0}) - (\overline{C}_{post}^{0} - \overline{C}_{pre}^{0})$$

• Difference in differences!

$$\widehat{CE}_{post} = (\overline{Y}_{post} - \overline{Y}_{pre}) - (\overline{C}_{post} - \overline{C}_{pre})$$

## Most important assumptions

#### **Parallel trends**

$$\beta \cdot Time = (\bar{C}_{post}^0 - \bar{C}_{pre}^0)$$

Time effect is the same for the treated and the control unit

#### No interference / spillover

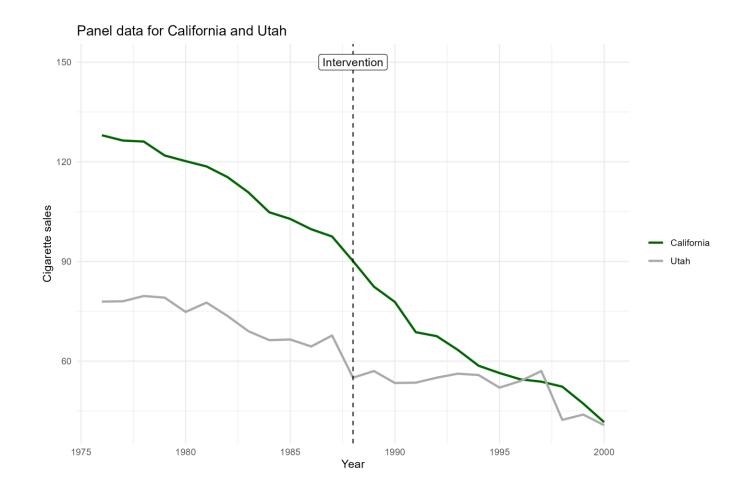

$$\bar{C}_{post} = \bar{C}_{post}^0$$

The control does not receive any intervention effect

## Most important assumptions

Can we assume parallel trends?

• At least superficially plausible ©

#### **Practical**

Work in pairs/groups!
